25X1

CONSTITUTE TO THE STATE OF THE

- As the old plant, which was destroyed during the war, had only two turbines and four boilers, the turbine and boiler house had to be extended to the west to install the two additional turbines and the four additional boilers. Auxiliary buildings were also extended to the west. The turbines and boilers were numbered consecutively from east to west. The required construction work necessitated the lapse of time between the starting of the second and the third turbine.
- 6. The lack of detailed sketches complicated the assembly. One general plan only was available, and all detailed sketches had to be prepared. Even though the complete installation of the Mechtal power plant was presumably dismantled, misdirected shipments and the demage to material caused by bad meather and improper handling resulted in a shortage of many parts, such as ball mills, blovers and 60 percent of the boiler parts. The missing parts had to be manufactured in the auxiliary morkshops.
- 7. After the completion of the second section of the main building, all damaged auxiliary installations were rebuilt. The construction of a second dam farther downstream was also started during this period. This dam was being constructed to raise the water level about 3 meters; the raised water level was required for the construction of the plant's third section, which was to be started in 1950. Tans or sketches for this third section were not yet available. Fore turbines and boilers were to be installed to increase the total plant capacity from 200,000 km to 400,000 km. Two Toylet turbines with a capacity of 100,000 km each, and five large Toylet boilers were to be installed.
- 8. The Kurskhov GEES, before the war already one of the important sources of power in the U.S.R.R. was to become one of the largest and most modern installations of its kind and the first high pressure power plant in the U.S.S.R.
- 9. It eight boilers available at the power plant in 1949 were of the same type. They were high capacity radiation boilers of the Babcock Firm in Oberhausen (K 52/A 32), and were designed for fueling with coal dust. Each one had a heating surface of 800 square maters, a working pressure of 80 atmos., and a super heat of 500°C. Each boiler consumed 20 tons of coal per hour and generated about 120 to 140 tons of steam during the same time. It was planned that two boilers would be operated for one turbine, but changes were possible. Until December 1949, three turbines were driven by seven boilers.

Improvement facilitated the collection and disposal of the slag in liquid condition. Thus ask dust and crusts on the boiler walls were eliminated. The glowing slag was utilized for a further increase of capacity.

10. The boilers To 1 to 5 and To 7 each had two pulverizers (Kucel-muchle), grinding the coal to dust for fueling. The pulverizers were constructed at the Babcock Firm and were called Babcock tube mills. They operated with 21 rpm and had a canacity of 17 tons of each per hour. Poilers To 6 and 8 each had two Coviet pulverizers of the "Sha 16" type constructed at the Kamenski (sic) Firm in Todolsk (55023 1/37050 T). These pulverizers ground 24 tors of coal per hour. Tach of the two inclined hoists transported 270 tons of coal per hour. Each boiler was equipped with

blowers (** thank	stan) on the etalrem	la nintrami	Thomas his	

two blowers ("xhaustor) on the stoker's mlatform. These blowers sucked in the coal dust and blow it into the fire. Foilers To 1 to 5 had German blowers, and the other boilers were fitted with loviet types. Each boiler was fitted with two German ventiletors to supply warm air.

- ll. The coal gases mere purified by eight electric filters made by the Lurgi Firm in Frenkfurt/Main. The plant had a total of 11 suction draughts (Gangzuege). Five of these draughts, constructed at the Babcock Plants, mere fitted to five different boilers. The other six suction draughts mere of Toviet origin. The mere fitted to each of the remaining three boilers.
- 12. The turbines were of the two-stage type with a high pressure stage utilizing steam at 78 abmos, and 500°C super heat, and a low pressure stage. Including the generator the turbines were 21 meters long and 4 to 5 meters wide. Each turbine was fitted with three tapping points for steam with a pressure of 1, 3, and 23 ctags. This steam was mostly used for central reating.
- 13. Il turbines were in operation at the same time. There were no long interruptions in their operation. The plant supplied power in various voltages up to 100,000 volts. The 100,000 volt power was delivered to the lonets basin.
- 14. The reservoir had a total length of about 8 km and an average ridth of 1 km. The first dam, a concrete structure located farther upstream, existed in 1845. The dam was equipped with gates. second dom was still under construction with sand and earth being piled up. A railroad bridge crossed the reservoir upstream from the first dam. During the same period apartment bouses, a school, a hos ital, and other public buildings were constructed in the vicinity.
